

Why the Reconstruction Loop Broadens: Three Structural Transitions

Each row shows how a new dependency changes the engineering decision and therefore the operator choice.

A · Local fit → reusable scope

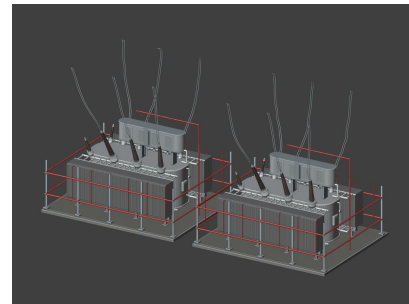

B01: local fit

define a local comparison domain, then fit pose and size

repetition introduces invariance

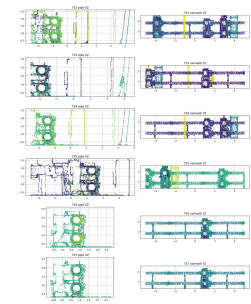

B08: shared equipment

two installations reuse one shared MASTER

reuse boundary becomes testable

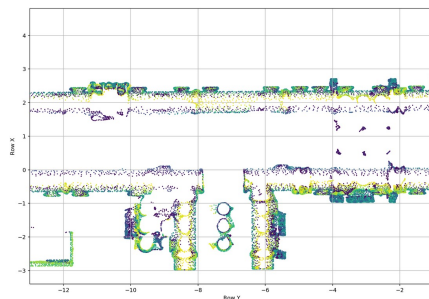

B15: revise reuse boundary

finite site geometry moves outside the shared asset

B · Object geometry → connected representation

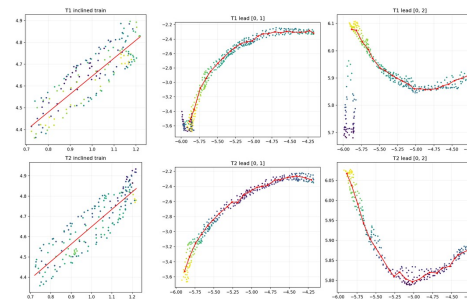

B20: ports and routes

existing equipment ends become explicit ports

relationship constraints appear

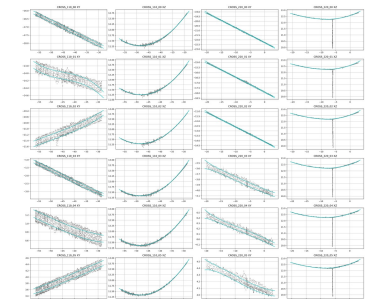

B23: change representation

the connection is reformulated from straight to curved

endpoint and topology constraints scale

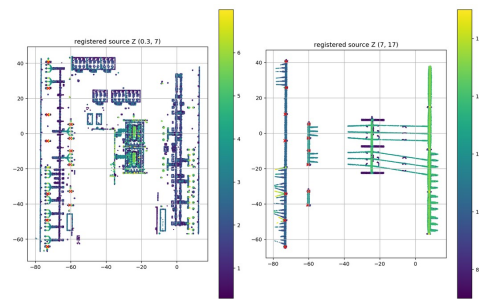

B29: relational constraints

continuity and endpoint constraints scale across subsystems

C · Scheduled addition → gap/state-driven closure

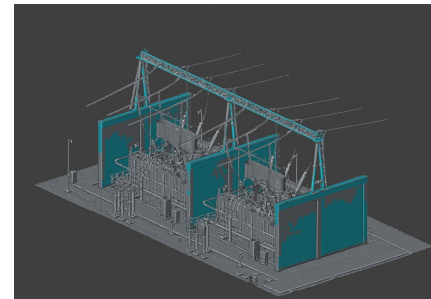

B25: unexplained geometry

large unexplained structures remain in the scene

coverage becomes a task signal

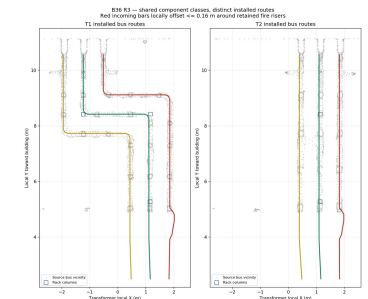

B26: reconstruct selected gaps

coverage selects which missing structures to reconstruct next

new geometry must fit the existing world

B36: state-constrained insertion

new geometry must fit inherited endpoints and occupied space

Descriptive evidence from the B01–B36 record. The figure explains how the reconstruction problem changes; it does not propose a universal complexity taxonomy.
