

Persistent State Enables Cross-Batch Composition—and Propagates Errors

Later batches consume earlier masters, terminals, and endpoints; B15 shows the same mechanism propagating a wrong shared abstraction.

shared abstraction inherited across installations

B15: inherited abstraction can propagate an error

An early reusable representation gave multiple GIS installations the same finite bus-spool extent. The shared assumption produced overlaps where actual site separations differed. Recovery revised the MASTER/site boundary: reusable equipment stayed shared, while finite pipe sections and supports moved to site-specific scope.

B36 preservation burden

☐	36,615	previous objects unchanged
☐	7,114	previous station transforms unchanged
☐	2,798	protected files unchanged
☐	36,812	objects in the final B36 file

State-scale descriptors, not counts of independently verified physical assets.

The dependency chain documents composition through explicit external engineering state. No stateless control run is available, so the figure does not claim that persistence by itself improves accuracy.
